# 1 | Introduction

Given the opportunity to review the design document and related smart contract source code of the `Rentable` protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

## 1.1 About Rentable

`Rentable` is an NFT renting protocol that allows the holders of NFT collection (e.g., Decentraland LAND) to deposit into the protocol and get an `ORentable` token to represent the ownership. Each NFT collection also has a respective `WRentable` with the same token id, which is minted when rental starts and burnt on expiry. The renter will pay the required rent fee to the respective rentee. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of The `Rentable` Protocol

Item	Description
Issuer	<code>Rentable</code>

## 1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (<https://t.me/peckshield>), Twitter (<http://twitter.com/peckshield>), or Email ([contact@peckshield.com](mailto:contact@peckshield.com)).

Table 1.2: Vulnerability Severity Classification

Impact	High	Critical	High	Medium
	Medium	High	Medium	Low
	Low	Medium	Low	Low
		High	Medium	Low
		Likelihood		

## 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [8]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

Table 1.3: The Full List of Check Items

	Following Other Best Practices

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

## 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
<b>Configuration</b>	Weaknesses in this category are typically introduced during the configuration of the software.
<b>Data Processing Issues</b>	Weaknesses in this category are typically found in functionality that processes data.
<b>Numeric Errors</b>	Weaknesses in this category are related to improper calculation or conversion of numbers.
<b>Security Features</b>	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
<b>Time and State</b>	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
<b>Error Conditions, Return Values, Status Codes</b>	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
<b>Resource Management</b>	Weaknesses in this category are related to improper management of system resources.
<b>Behavioral Issues</b>	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
<b>Business Logics</b>	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
<b>Initialization and Cleanup</b>	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
<b>Arguments and Parameters</b>	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
<b>Expression Issues</b>	Weaknesses in this category are related to incorrectly written expressions within code.
<b>Coding Practices</b>	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

## 2 | Findings

### 2.1 Summary

Here is a summary of our findings after analyzing the design and implementation of the `Rentable` protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	
Low	2	
Informational	0	
Total	3	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in [Section 3](#).

## 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 2 low-severity vulnerabilities.

Table 2.1: Key Rentable Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Improper Operator Handover Upon WToken Transfers of Expired Rents	Business Logic	Resolved
PVE-002	Low	Improved Validation on Protocol Fee Changes	Coding Practices	Resolved
PVE-003	Medium	Trust on Admin Keys	Security Features	Confirmed

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

## 3 | Detailed Results

### 3.1 Improper Operator Handover Upon WToken Transfers of Expired Rents

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Medium
- Target: Multiple Contracts
- Category: Business Logic [6]
- CWE subcategory: CWE-841 [3]

#### Description

The `Rentable` protocol manages the deposited NFT collections with the associated `ORentable` and `WRentable` to keep track of the current rentee as well as the potential renter. The transfers of the associated `ORentable` and `WRentable` will require the necessary updates due to the rentee/renter changes. While examining the logic behind the `WRentable` transfer, we notice an issue that may unnecessarily grant extra roles to the recipient.

To elaborate, we show below the `afterWTokenTransfer()` routine, which is invoked whenever the `WRentable` token is transferred. This routine has a rather straightforward logic in examining whether the rent is expired. If expired, the underlying token's update role is properly transferred back to the current `ORentable` owner. However, the current implementation has the logic in invoking the `delegatecall` of `postWTokenTransfer()`, which grants the `WRentable` recipient with the underlying token's update role – even if the `WRentable` is now expired!

```
873     function afterWTokenTransfer(  
874         address tokenAddress,  
875         address from,  
876         address to,  
877         uint256 tokenId  
878     ) external override whenNotPaused onlyWToken(tokenAddress) {  
879         _expireRental(address(0), tokenAddress, tokenId, true);  
880  
881         address lib = _libraries[tokenAddress];
```

```

882     if (lib != address(0)) {
883         // slither-disable-next-line unused-return
884         lib.functionDelegateCall(
885             abi.encodeWithSelector(
886                 ICollectionLibrary.postWTokenTransfer.selector,
887                 tokenAddress,
888                 tokenId,
889                 from,
890                 to
891             ),
892             ""
893         );
894     }
895 }

```

Listing 3.1: `Rentable::afterWTokenTransfer()`

To correct, there is a need to check the current `rent` status. If the `rent` becomes expired, there is a need to inform the subsequent `postWTokenTransfer()` call so that it should avoid granting the update role to the recipient.

**Recommendation** Revise the transfer logic of `WRentable` to properly manage the update role of the underlying `NFT` collections.

**Status** The issue has been fixed by this commit: 4613d41.

## 3.2 Improved Validation on Protocol Fee Changes

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `Rentable`
- Category: Coding Practices [5]
- CWE subcategory: CWE-1126 [1]

### Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The `Rentable` protocol is no exception. Specifically, if we examine the `Rentable` contract, it has defined a number of protocol-wide risk parameters, such as `_fee` and `_paymentTokenAllowlist`. In the following, we show the corresponding routines that allow for their changes.

```

169     function setFee(uint16 newFee) external onlyGovernance {
170         uint16 previousFee = _fee;
171
172         _fee = newFee;
173     }

```

```

174     emit FeeChanged(previousFee, newFee);
175 }
176
177 /// @dev Set fee collector address
178 /// @param newFeeCollector fee collector address
179 function setFeeCollector(address payable newFeeCollector)
180     external
181     onlyGovernance
182 {
183     require(newFeeCollector != address(0), "FeeCollector cannot be null");
184
185     address previousFeeCollector = _feeCollector;
186
187     _feeCollector = newFeeCollector;
188
189     emit FeeCollectorChanged(previousFeeCollector, newFeeCollector);
190 }
191
192 /// @dev Enable payment token (ERC20)
193 /// @param paymentToken payment token address
194 function enablePaymentToken(address paymentToken) external onlyGovernance {
195     uint8 previousStatus = _paymentTokenAllowlist[paymentToken];
196
197     _paymentTokenAllowlist[paymentToken] = ERC20_TOKEN;
198
199     emit PaymentTokenAllowListChanged(
200         paymentToken,
201         previousStatus,
202         ERC20_TOKEN
203     );
204 }

```

Listing 3.2: Rentable::setFee() and Rentable::setFeeCollector()

These parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. Based on the current implementation, certain corner cases may lead to an undesirable consequence. For example, an unlikely mis-configuration of `_fee` may charge unreasonably high fee in the `rent` payment, hence incurring cost to borrowers or hurting the adoption of the protocol.

**Recommendation** Validate any changes regarding these system-wide parameters to ensure they fall in an appropriate range.

**Status** The issue has been fixed by this commit: 4613d41.

### 3.3 Trust Issue of Admin Keys

- ID: PVE-003
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: Rentable
- Category: Security Features [4]
- CWE subcategory: CWE-287 [2]

#### Description

In the Rentable protocol, there is a special administrative account, i.e., governance. This governance account plays a critical role in governing and regulating the system-wide operations (e.g., configure various settings, pause/unpause the protocol, as well as update the proxy implementation). It also has the privilege to control or govern the flow of assets within the protocol contracts. In the following, we examine the privileged account and the related privileged accesses in current contracts.

```

128     function setLibrary(address tokenAddress, address libraryAddress)
129         external
130         onlyGovernance
131     {
132         address previousValue = _libraries[tokenAddress];
133
134         _libraries[tokenAddress] = libraryAddress;
135
136         emit LibraryChanged(tokenAddress, previousValue, libraryAddress);
137     }
138
139     /// @dev Associate the otoken to the specific wrapped token
140     /// @param tokenAddress wrapped token address
141     /// @param oRentable otoken address
142     function setORentable(address tokenAddress, address oRentable)
143         external
144         onlyGovernance
145     {
146         address previousValue = _orentables[tokenAddress];
147
148         _orentables[tokenAddress] = oRentable;
149
150         emit ORentableChanged(tokenAddress, previousValue, oRentable);
151     }
152
153     /// @dev Associate the otoken to the specific wrapped token
154     /// @param tokenAddress wrapped token address
155     /// @param wRentable otoken address
156     function setWRentable(address tokenAddress, address wRentable)
157         external
158         onlyGovernance
159     {

```

```
160     address previousValue = _wrentables[tokenAddress];  
162     _wrentables[tokenAddress] = wRentable;  
164     emit WRentableChanged(tokenAddress, previousValue, wRentable);  
165 }
```

Listing 3.3: Example Privileged Operations in `Rentable`

We understand the need of the privileged functions for proper contract operations, but at the same time the extra power to these privileged accounts may also be a counter-party risk to the contract users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among protocol users.

**Recommendation** Promptly transfer the privileged account to the intended DAO-like governance contract. All changes to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

**Status** The issue has been confirmed by the team. The team clarifies that the governance account will be managed by a multi-sig account.

## 4 | Conclusion

In this audit, we have analyzed the design and implementation of the `Rentable` protocol, which is an NFT renting protocol that allows the holders of NFT collection (e.g., Decentraland LAND) to deposit and get an `ORentable` token to represent the ownership. Each NFT collection also has a respective `WRentable` with the same token id, which is minted when rental starts and burnt on expiry. The current code base is clearly organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that `Solidity`-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
